How does a microgrid work?

In normal operation, the microgrid is connected to the main grid. In the event of disturbances, the microgrid disconnects from the main grid and goes to the islanded operation. In the islanded mode operation of a microgrid, a part of the distributed network becomes electrically separated from the main grid, while loads are supported by local DERs.

Can a microgrid connect and disconnect from the grid?

What constraints should a microgrid satisfy?

For instance, in a microgrid with corresponding V_i and ω_i should satisfy following constraints $V_i \leq V_{max}$, $\omega_i \leq \omega_{max}$, $P_i \leq P_{max}$, $Q_i \leq Q_{max}$ where V_i and ω_i are the maximum voltage deviations, respectively. power of the i th DER. of microgrid, the DER voltage and angular frequency, and P_i , Q_i are enforced by the grid.
